ENGINEERING

Outline

- Background
- Motivation
- Experimental Setup
- Results
- Insights

Background

Food Waste and Environmental Microbiomes

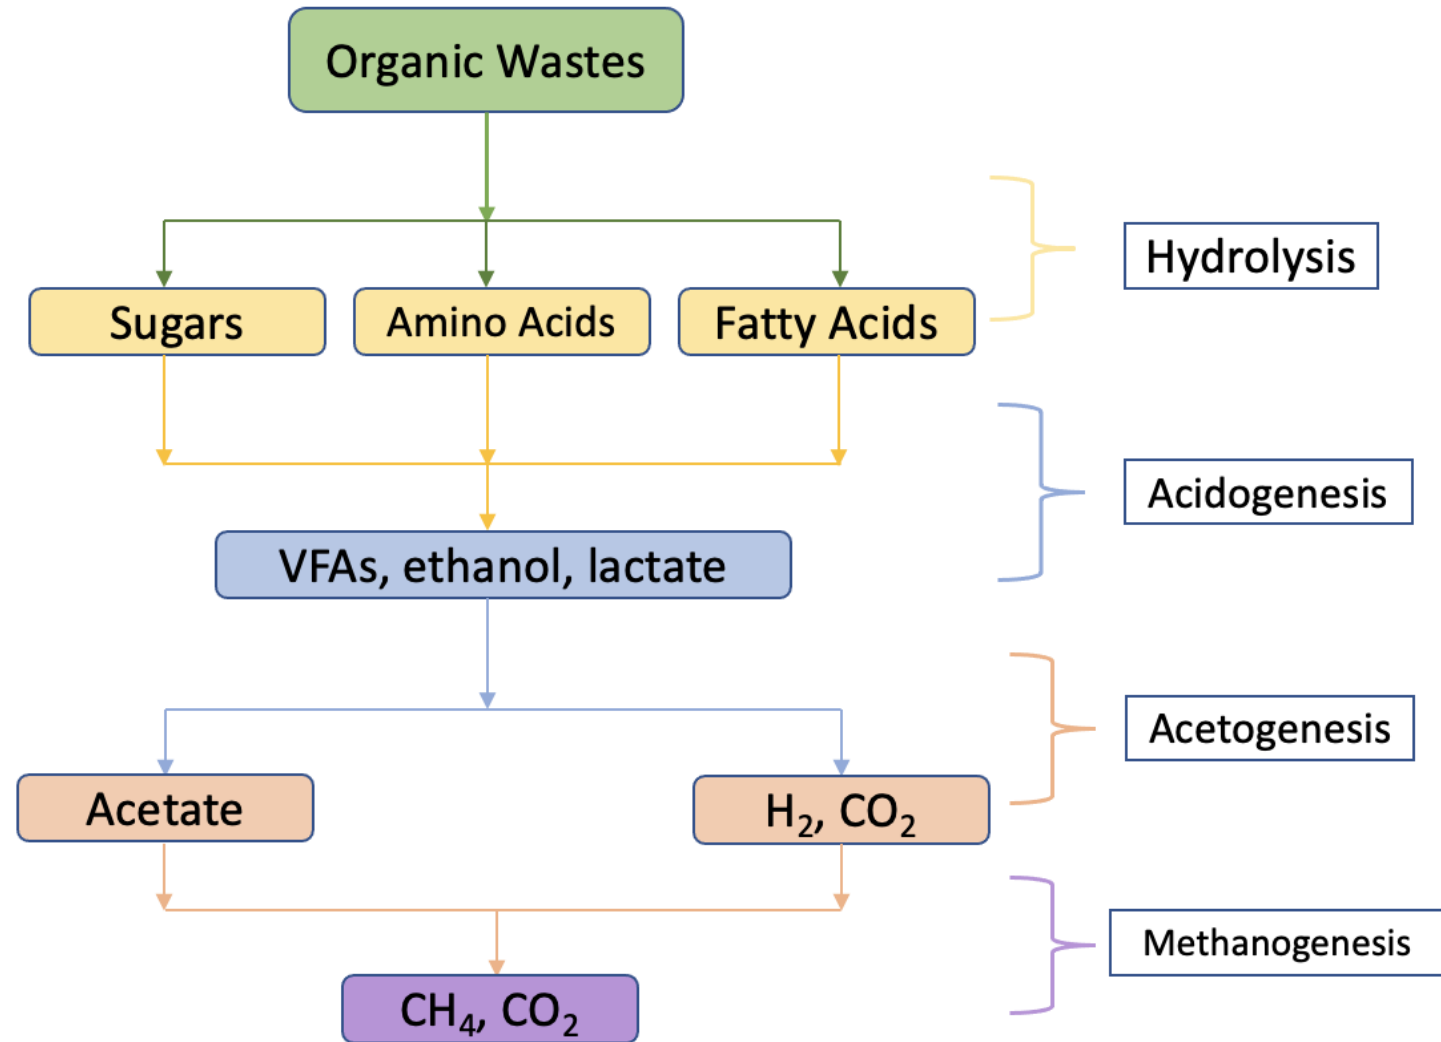

Background

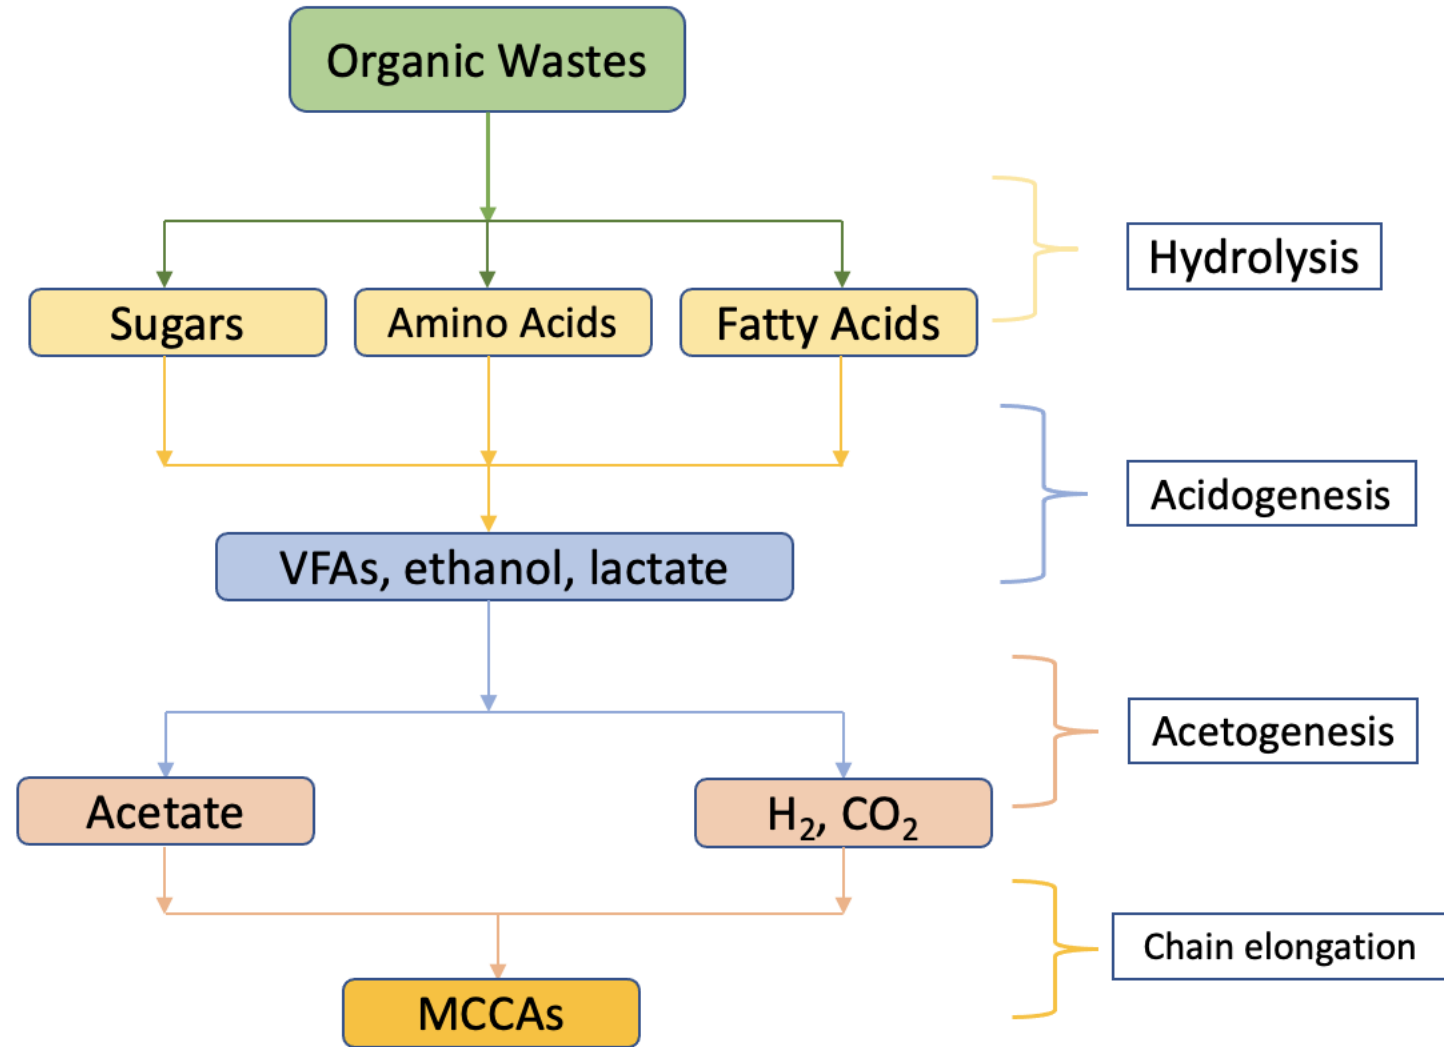

Organic Waste

Conventional Anaerobic Digestion

Chain Elongation Process

Medium Chain Carboxylic Acids (MCCAs)

- Consist of 6 to 12 atoms of carbon

- Dietary-nutritional supplements, especially as medium-chain triglycerides (MCTs),
- Production of personal care products, pharmaceuticals, dyes, and antimicrobials,
- Production of liquid transportation fuels has gain great attention and is in progress.

Motivation

Motivation

Experimental Setup and Methods

Experimental Setup

Experimental Setup

Operating Parameters:

- Enriched biomass with chain elongators
- Non-sterile feedstock: real food waste
- HRT: 6 days
- pH: 5.5
- Temperature: 37°C
- No external electron donor

Methods

Analyzing Samples:

- sCOD
- $\text{NH}_4\text{-N}$
- Proteins
- Fats
- Carbohydrates

- Headspace Gas
- Short and Medium Chain Fatty Acids
- Metagenomic and Metatranscriptomic analysis

Results

Results

Influent and effluent COD rate was relatively constant.
This is common in the chain elongation process.

Short and Medium Chain Carboxylic Acids

- Acetic acid – precursor for reverse β -oxidation - is low.
- Butyric acid – one cycle of reverse β -oxidation – is the most abundant carboxylic acid.
- Hexanoic acid – second cycle of reverse β -oxidation – the second most abundant carboxylic acid and the most abundant MCCA.

Insights

Insights

- 46% of COD in food waste was fermented to VFAs or MCCAs
- 17% of COD in food waste was converted to MCCAs
- Microbial community changed after adding food waste
 - A relatively simple microbial community emerged
 - 10 genera accounted for > 90% of reads
 - Relative abundance of *Caproicprodugens* increased
 - Relative abundance of an Unclassified Ruminococcaceae decreased
 - New simple fermenting bacteria arose

NEXT STEPS:

- Metagenomic and metatranscriptomic analyses
